# (6 – 3) Streams and File Processing in C++

Instructor - Andrew S. O'Fallon CptS 122 (February 15, 2019) Washington State University

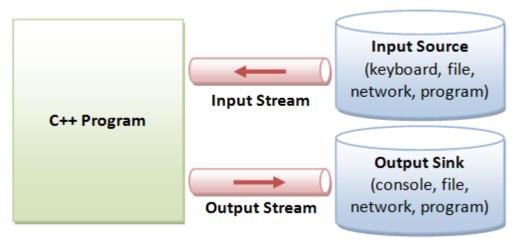

# What is a Stream? A Refined Definition

- A sequence of objects (generally just considered bytes) that flow from a device to memory or from memory to a device
- For input operations, the bytes flow from the device (i.e. keyboard, network connection, disk, etc.) to main memory
- For output operations, the bytes flow from main menu to the device (screen, printer, etc.)

#### **Abstraction of a Stream**

Internal Data Formats:

- Text: char, wchar\_t
- int, float, double, etc.

**External Data Formats:** 

- Text in various encodings (US-ASCII, ISO-8859-1, UCS-2, UTF-8, UTF-16, UTF-16BE, UTF16-LE, etc.)
- Binary (raw bytes)
- Image courtesy of: <a href="http://www.ntu.edu.sg/home/ehchua/programming/cpp/images/IOstreams.png">http://www.ntu.edu.sg/home/ehchua/programming/cpp/images/IOstreams.png</a>

### **Analogy for a Stream**

#### A conveyer belt

- You can place an item in sequence on the belt,
   i.e. into the stream (insertion or output operation)
- You can remove an item in sequence from the belt, i.e. take from the stream (extraction or input operation)

# Classic Streams vs. Standard Streams

- The classic input/output streams for C++ supported byte-sized chars, which represented the ASCII characters
- Many alphabets require more characters than can be represented by a byte and the ASCII character set does not provide the characters
  - The *Unicode* character set provides these ones
- C++ provides standard stream libraries to process Unicode characters (wchar t)

### Standard Streams in C++ (1)

- For standard input/output streams, include <iostream>
  - cin is a predefined object of class istream and is connected to the standard input device (i.e. keyboard)
    - cin >> var // cin applying stream
       extraction operator stops at whitespace
       for strings
  - cout is a predefined object of class ostream and is connected to the standard output device (i.e. screen)
    - cout << var // cout applying stream insertion operator

### Standard Streams in C++ (2)

- Member function getline() will read a line from the stream
  - Inserts a null character at the end of the array of characters, removes and discards the '\n' from the stream (i.e. stored as a C string)

# Recall the File Processing Algorithm!

- Step 1: open the desired file
  - Opening is based on filename and permissions (read, write, or append)
  - Associates a file with a stream
- Step 2: process the file
  - Read data from the file
    - Does not affect file
  - Write data to the file
    - Completely overwrites existing file
  - Add data to the end of the file
    - Retains previous information in file
- Step 3: close the file
  - Disassociates a file from a stream

### Files Streams in C++ (1)

- For input/output streams to work with files,
   include <fstream>
  - ifstream objects enable input from a file
  - ofstream objects enable output to a file
  - fstream objects for input from and output to a file
- Associate file with a file stream either during construction (applying the constructor or by calling open ())
  - fstream fstr("filename.txt") // an instantiation of fstream object Or fstr.open("filename.txt") // after instantiation

## Files Streams in C++ (2)

#### Read from files using:

- fstr >> var; // applying the stream
   extraction operator stops at whitespace
   for strings
- fstr.getline () // to read entire line into a character array
  - Stored as a C string
- Write to files using:
  - fstr << var; // applying the stream
    insertion operator</pre>

### Files Streams in C++ (3)

- Each file ends with an end-of-file marker (EOF)
  - check if at end of file using fstr.eof()
- Close a file using:

```
- fstr.close();
```

### **Closing Thoughts on Files**

- Files are required for many applications
- Files may be created and manipulated in any manner appropriate for an application
